6 Known issues **8**
6.1 Windows: Issues during installation: username contains a space character 8
6.2 Windows: Spyder installation fails: your processor is not x86 (Intel/AMD processors) . 8
6.3 Mac: Wrong installer is used 9
6.4 Mac: No shortcut to Spyder is created/Spyder does not appear in Spotlight 9

1 Installing Python

This course aims to teach you the fundamentals of Python - but before we can even start, we have to install Python on your computer. **You are free to install Python in any way you want, and use any editor that you wish, but you will be responsible for your own technical support.** *If you know what you are doing, go ahead.* If you are new to Python or programming in general, I recommend following the steps below.

2 Installing Miniconda (small Anaconda)

There are many ways to install Python, but in this course, we will use Miniconda. You may have heard of Anaconda as a way to install Python, but installing Anaconda is much bigger (Anaconda starts at ~4.5GB, Miniconda starts at ~400MB), and includes a lot of functionality that we will not be using in this course. Miniconda is a cut-down version of Anaconda that allows us to pick and choose what functionality we need.

Installation instructions and links are provided in the sections below. If the installation instructions below fails, you can view installation instructions for Miniconda for Windows, macOS, and Linux. Once installed, make sure to open the relevant application mentioned in the sections below.

2.1 Windows

Download and run the installer (link). During the installation, check that the path **does not contain a space character**. **If your username contains a space, read this.** Follow the prompts, taking note of the option to "Create shortcuts". **Ensure this option is ticked.** If you face any issues during installation, check the known issues section. **If your computer does not use an Intel or AMD processor, read this.**

After installation, open your start menu and search for **Anaconda Prompt**, and open it.

2.2 macOS

Download and run the installer appropriate for your machine, depending on whether your computer runs on Apple Silicon (installer link) or Intel (installer link). You can check whether your machine runs on Apple Silicon or Intel by following Apple's instructions. If you face any issues during installation, check the known issues section. Follow the prompts and finish the installation.

After installation, open a **Terminal** window, which you can start with Spotlight (Cmd+Space) and searching for Terminal.

3 Setting up Miniconda and Spyder

After finishing installation and opening the relevant application, you should see a window similar to the below:

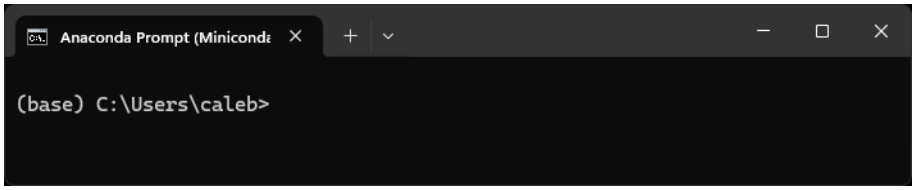

Figure 1: On both Windows and macOS/Linux, you should see something like this. The line should be prefixed with '`(base)`' on both Windows and macOS/Linux.

This is a **command-line interface** (CLI), and is one method of interacting with your computer. In this course, we'll use this mainly to interact with and set up Python. To begin with, type `python` into the window, and hit enter.

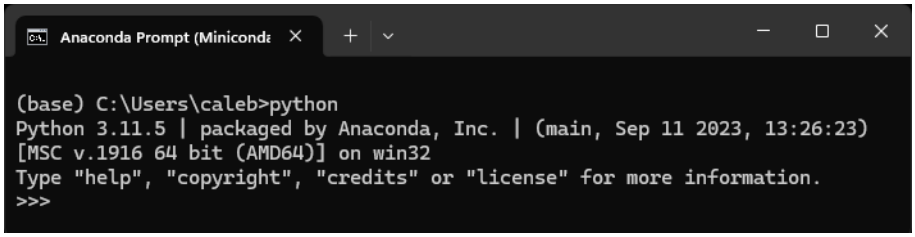

Figure 2: Something similar to this should appear. The specific version of Python may be different, but make sure that the first number is a 3. The line should be prefixed with '`>>>`'.

We just opened a Python *console*, which allows us to interact directly with Python. Type the following lines into the console, and observe what is printed back to you.

```
14 * 9
121 / (2 * 3 + 5)
```

The computer should show `126` and `11.0` in response - the mathematical results of each operation.

Type `exit()` in. After that, the start of the line should no longer be `>>>`. Your console should look like fig. 3). Don't close the window yet!

While the Python console is useful for short code snippets, other programs are better suited for coding longer programs. In this course, we'll use Spyder as our application to interface with Python.

To install Spyder, type into the prompt the following line, give it a few seconds to load, and install it (fig. 4). You may have to confirm several actions, so pay attention to it.

```
conda install -c conda-forge spyder=6
```

Once installed, some shortcuts to launch Spyder *should* have been added. Open the start menu (on Windows) or Spotlight (on macOS, using Cmd+Space) and search for Spyder to launch it. This is

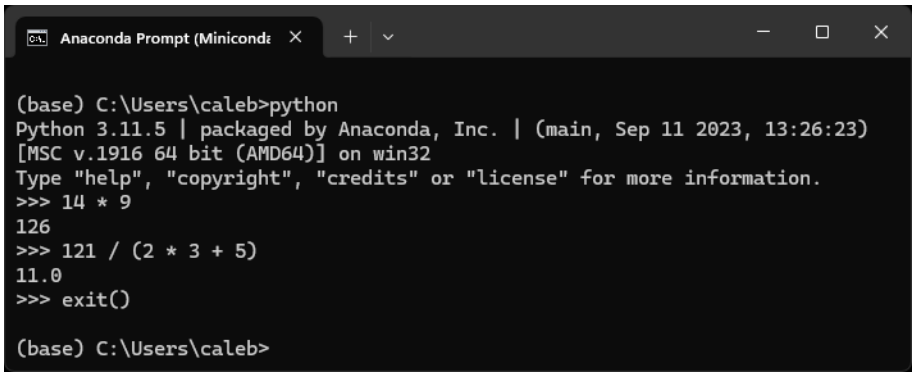

Figure 3: After `exit()`, your terminal should look like this. The last line should have a '`(base)`' prefix.

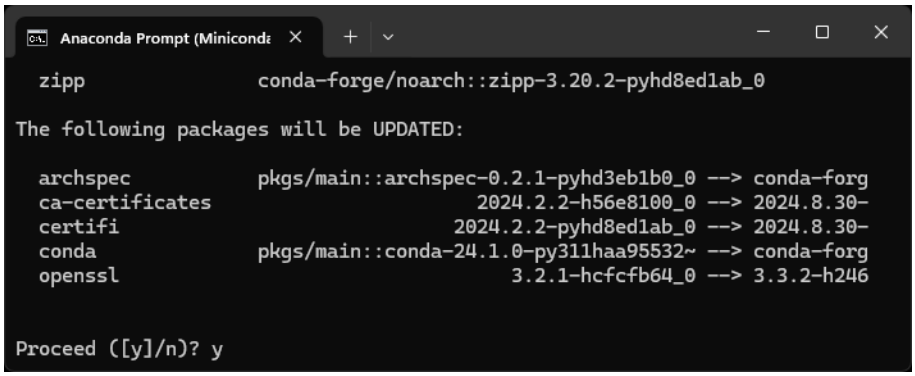

Figure 4: Proceed with the installation by entering '`y`'.

the preferred way to launch Spyder. If no shortcuts were added, enter `spyder` into the Anaconda Prompt/Terminal to launch Spyder. To add a shortcut on macOS, read this

3.1 Setting up Spyder

There are many applications in which you can develop Python programs in, but this course will focus on using Spyder. Spyder is an application meant to ease Python development. In a single application (Spyder), you can edit a program, run it, and debug it.

Before moving on, let's make sure we all have the same interface. Use the *menu bar* to navigate to View > Window layouts > Default layout, like in fig. 5. **If your accidentally change your interface and you need help resetting it, remember this!**

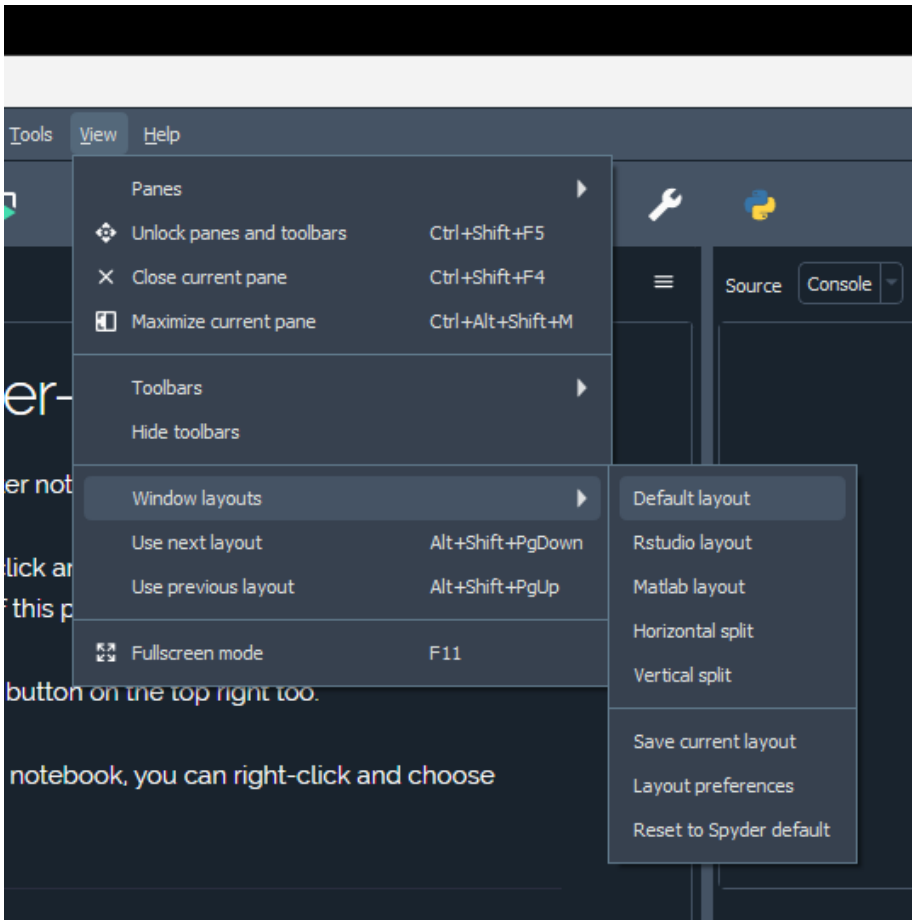

Figure 5: This top bar with 'View' and 'Help' is known as the menu bar.

4 Online Python interpreters

Finally, there are also online Python interpreters. No installation is required, you only need to visit a webpage. You can search for 'online Python interpreter'.

As compared to Spyder and other desktop applications, its functionalities are limited, and they tend

to be slower, as they work over the internet. You may use it for a quick script when no other interface is available.

5 Maintaining Spyder and Miniconda

These instructions are for Spyder installations performed with the above. **Do not use these if you installed Spyder via the standalone Spyder installer, i.e. not through Miniconda.**

5.1 Updating Spyder

Occasionally, when opening Spyder, a prompt may pop up informing you that a new update is available. You can untick the box to check for updates, but **do not update it through that window!** You may ignore most updates, but if you want to update it, you can open Anaconda Prompt and enter the following:

```
conda update spyder
```

This will update Spyder to the latest available version. Alternatively, if you want to install a specific version, you can use specify the version number with `conda install spyder=<version>`, for example:

```
conda install spyder=6.0.5
```

5.2 Uninstalling Spyder

To uninstall Spyder, enter the following into Anaconda Prompt:

```
conda remove spyder
```

This will leave Miniconda and your Python installation intact.

5.3 Uninstalling Miniconda

Uninstalling Miniconda will remove your Python installation and any packages installed with it. This includes Spyder, and the notebook extension installed earlier.

As far as possible, you should refer to the latest instructions on Miniconda's website, but the instructions below may help.

5.3.1 Windows

Navigate to the installation directory of Miniconda. The default is `C:\Users\<your username>\miniconda3`. There should be a file `Uninstall-Miniconda3.exe` in the folder. Run it, and follow the prompts.

5.3.2 macOS (and Linux)

First, find where Miniconda is installed. If you are unsure, here is one way to check that may work. Open **Terminal**, and enter this line:

```
echo $CONDA_PREFIX
```

This will show a file path, for example, `/opt/miniconda3`. Take note of this file path. Enter the following line:

```
conda deactivate
```

`(base)` should no longer appear in your Terminal prompt. Then, enter the following line. If needed, replace `/opt/miniconda3` with the file path from earlier.

```
/opt/miniconda3/uninstall.sh
```

5.4 Jupyter Notebook in Spyder

Jupyter Notebook will not be used in this course. If you want to use Jupyter Notebook in Spyder, you can install it with this line in the Anaconda Prompt/Terminal:

```
conda install -c conda-forge spyder-notebook
```

Once installed, this will add a new Notebook tab in the editor. If it does not appear, try using the menu bar to navigate to View > Window layouts > Default layout.

6 Known issues

If the below does not help, one general solution is to install Spyder directly (link). This will function fine for the purposes of the course.

6.1 Windows: Issues during installation: username contains a space character

On Windows, the installation path of Miniconda includes a space character, e.g. `C:\Users\Caleb Tay\miniconda3`.

The space character causes issues during the installation.

Solution: We must create an installation path that does not include a space character, with appropriate permissions.

1. Open **Command Prompt as an administrator**. The window name should be "Administrator: Command Prompt".
2. Enter these exact commands, pressing enter after each line:

```
mkdir C:\miniconda3
takeown /f C:\miniconda3 /r /d y
icacls C:\miniconda3 /grant:r "%USERNAME%":(OI)(CI)F /t
```

3. Close the command prompt, and follow the installation instructions again, **changing the install path to** `C:\miniconda3` at the relevant step.

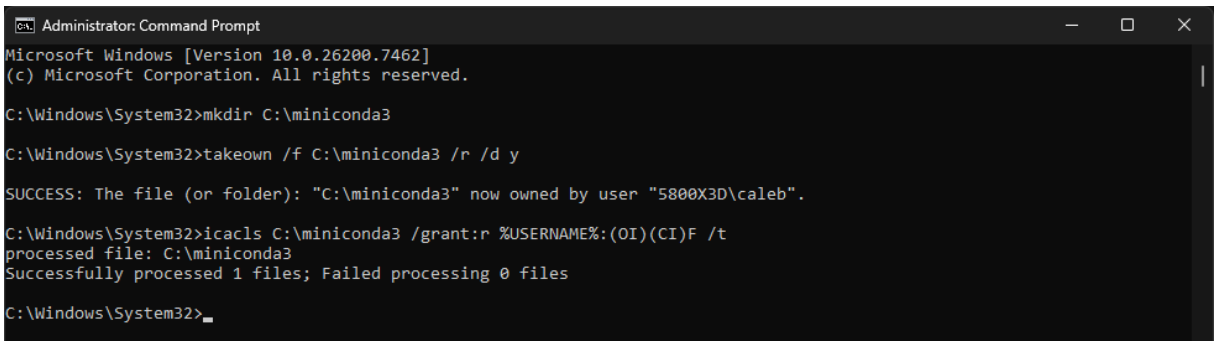

Figure 6: The command prompt should look similar to above, with your username showing up instead of `"5800X3D/caleb"`.

6.2 Windows: Spyder installation fails: your processor is not x86 (Intel/AMD processors)

While installation of Miniconda succeeds, installing Spyder with the above instructions say that "there is no option available". Spyder available through Miniconda is not built for arm64 (currently, only Qualcomm processors).

Your machine has to compile it so your machine can run it.

Solution: Open **Anaconda Prompt** and enter the following:

```
pip install spyder
```

You may have to disable "Smart App Control" in your settings temporarily - press the Windows start key and type in "smart app control" - the first option should be a settings page. Disable it, enter `spyder` in Anaconda Prompt, and you can enable it again.

6.3 Mac: Wrong installer is used

If you are using an older MacBook, you may be using the wrong installer, i.e. Intel vs Apple Silicon.

Solution: You may follow Apple's instructions to check what processor your computer uses.

If the above link does not work, a search for "macos check intel or apple silicon" should be helpful.

6.4 Mac: No shortcut to Spyder is created/Spyder does not appear in Spotlight

After installing Spyder through the Terminal, Spyder cannot be launched through Spotlight - no shortcut was created. One workaround is to open Terminal and type `spyder` in to run it, but this is not ideal.

Solution: Download this file, and unzip it (just double click it). An application with the Spyder logo should have appeared (like in fig. 7). Move this application, *not the .zip file*, into your Applications folder, which is likely a shortcut on the left side of your Finder window.

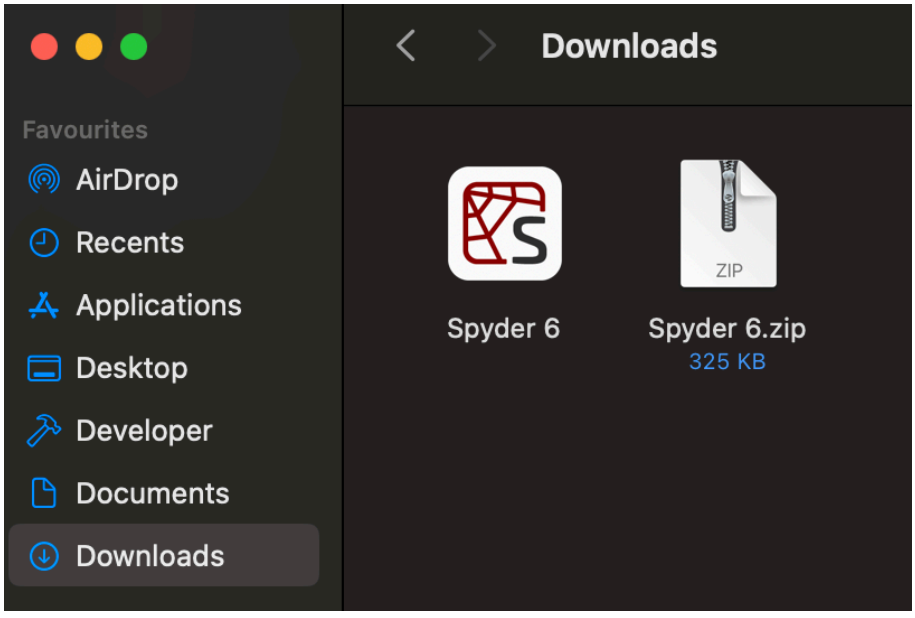

Figure 7: Double click the .zip file to extract the application with the Spyder logo. Move this application, *not the zip file*, to the Applications folder, which by default, is a shortcut on the left sidebar.

This app was constructed with the instructions here. You can right click the application and "View Contents". You may follow these instructions, replacing `/usr/local/bin/spyder3` with the path shown by what you see when you enter `which spyder` into Terminal.

When you run it for the first time, your Mac may block it from running. You have to open System Settings > Privacy and Security, and open it.
